

Multi-Qubit Operations using Scalable Techniques

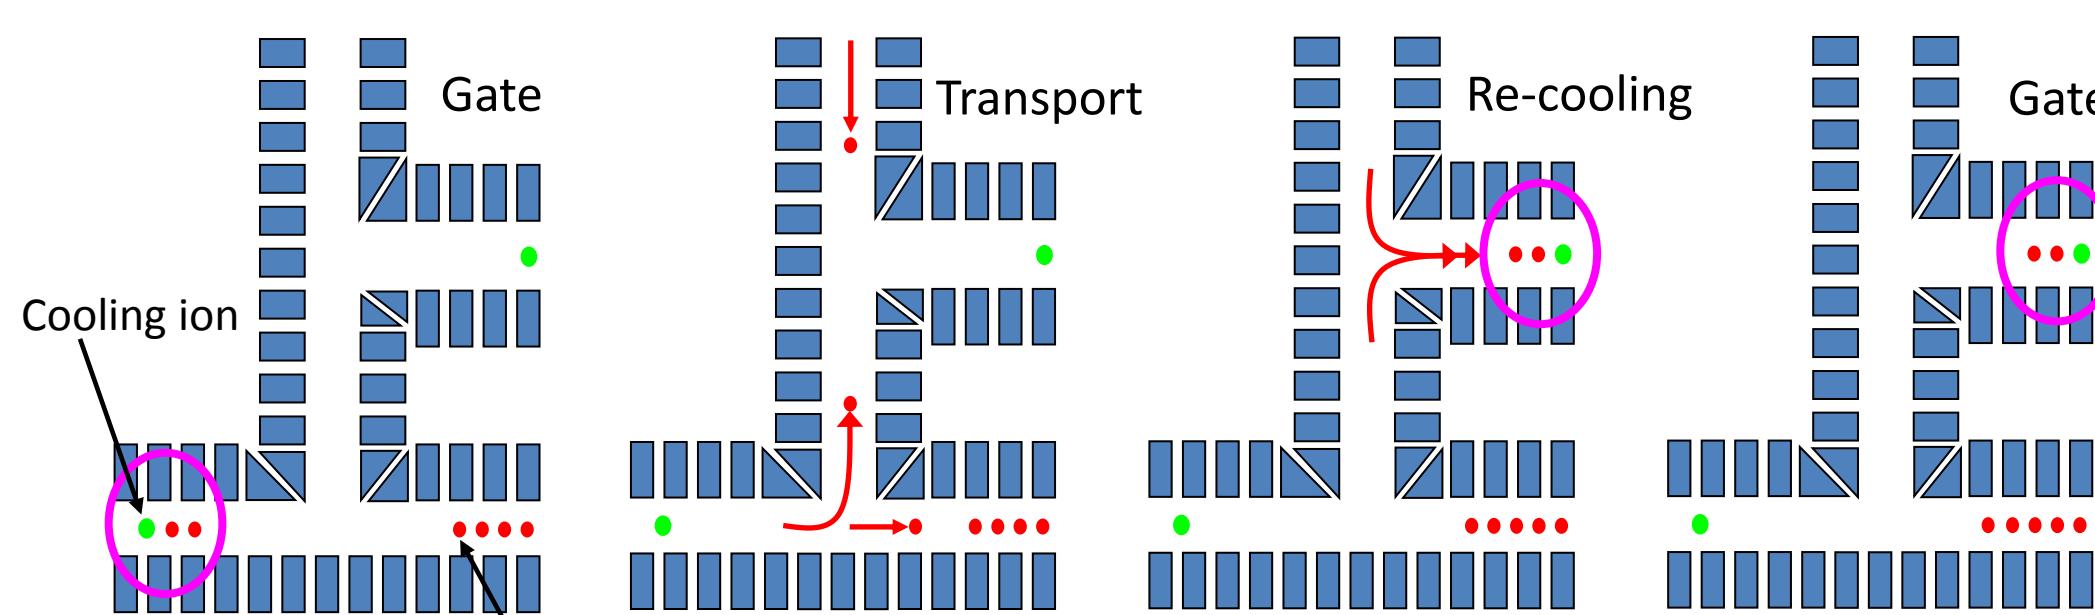

Ion Storage Group, NIST Boulder

J. P. Home, D. Hanneke, J. D. Jost, R. Bowler, J. Amini, Y. Lin, T-R. Tan, D. Leibfried, and D. J. Wineland

Scalable quantum registers

- A scalable quantum register must implement all the operations required for QIP
- Must use scalable methods – operations should be combined with information transport.
- Must implement operations in a manner which is consistent with a large-scale device
- Should be versatile – no hardware changes required for different tasks.

With trapped ions, one scalable architecture uses multi-zone traps
– transport of qubits involves moving the qubit ions themselves

- Requires qubit states robust against environmental perturbations
- Requires recooling prior to two-qubit gates due to imperfect control of transport and ambient heating (two-qubit gates only work for cold ions)

Arbitrary Control of 2-qubits (universal 2-qubit QIP)

D. Hanneke, et al, *Nature Phys.* **6** 13-16 (2010)

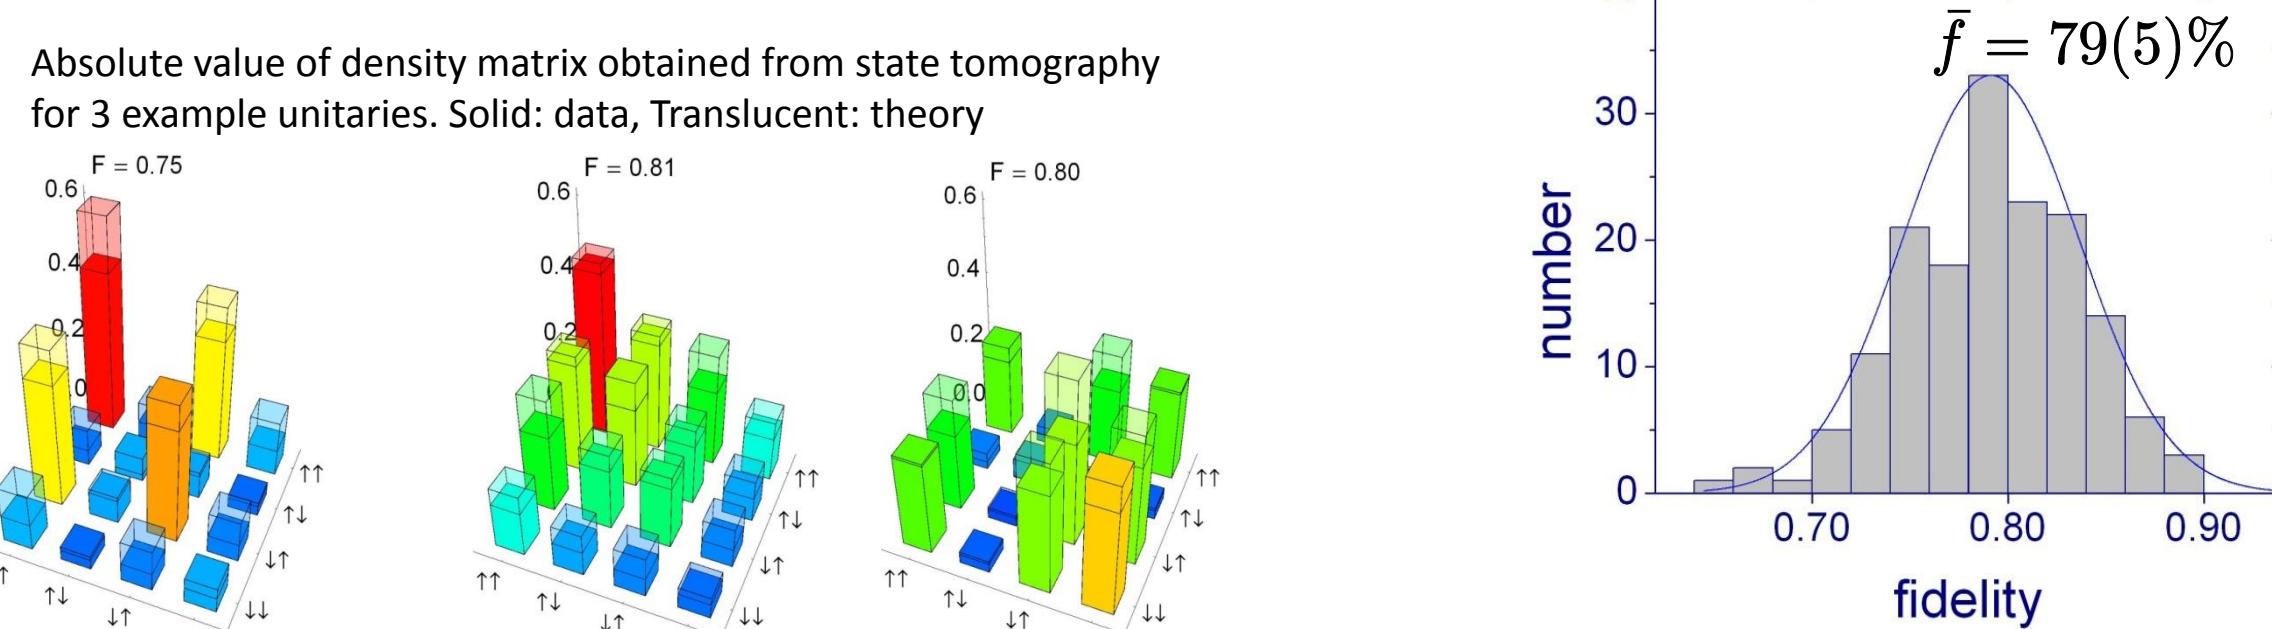

- We implement an arbitrary unitary operation in SU(4) using two-qubits
- 15 free parameters are inputs to single qubit gates.
 - 3 two-qubit gates required to reach all local equivalence classes

$$\begin{array}{c} \text{R}(\theta_A, \phi_A) \quad \text{R}_z(\phi_{zA}) \quad G \quad \text{R}(\alpha, 0) \quad G \quad \text{R}(\beta, \frac{\pi}{2}) \quad G \quad \text{R}(\phi_c, \phi_d) \quad \text{R}_z(\phi_{zd}) \\ | \quad | \\ \text{R}(\theta_B, \phi_B) \quad \text{R}_z(\phi_{Bz}) \quad \text{G} \quad \text{R}(\frac{3\pi}{2}, 0) \quad \text{G} \quad \text{R}(\frac{3\pi}{2}, \delta) \quad \text{G} \quad \text{R}(\phi_d, \phi_B) \quad \text{R}_z(\phi_{dB}) \end{array}$$

G is a two-qubit phase gate

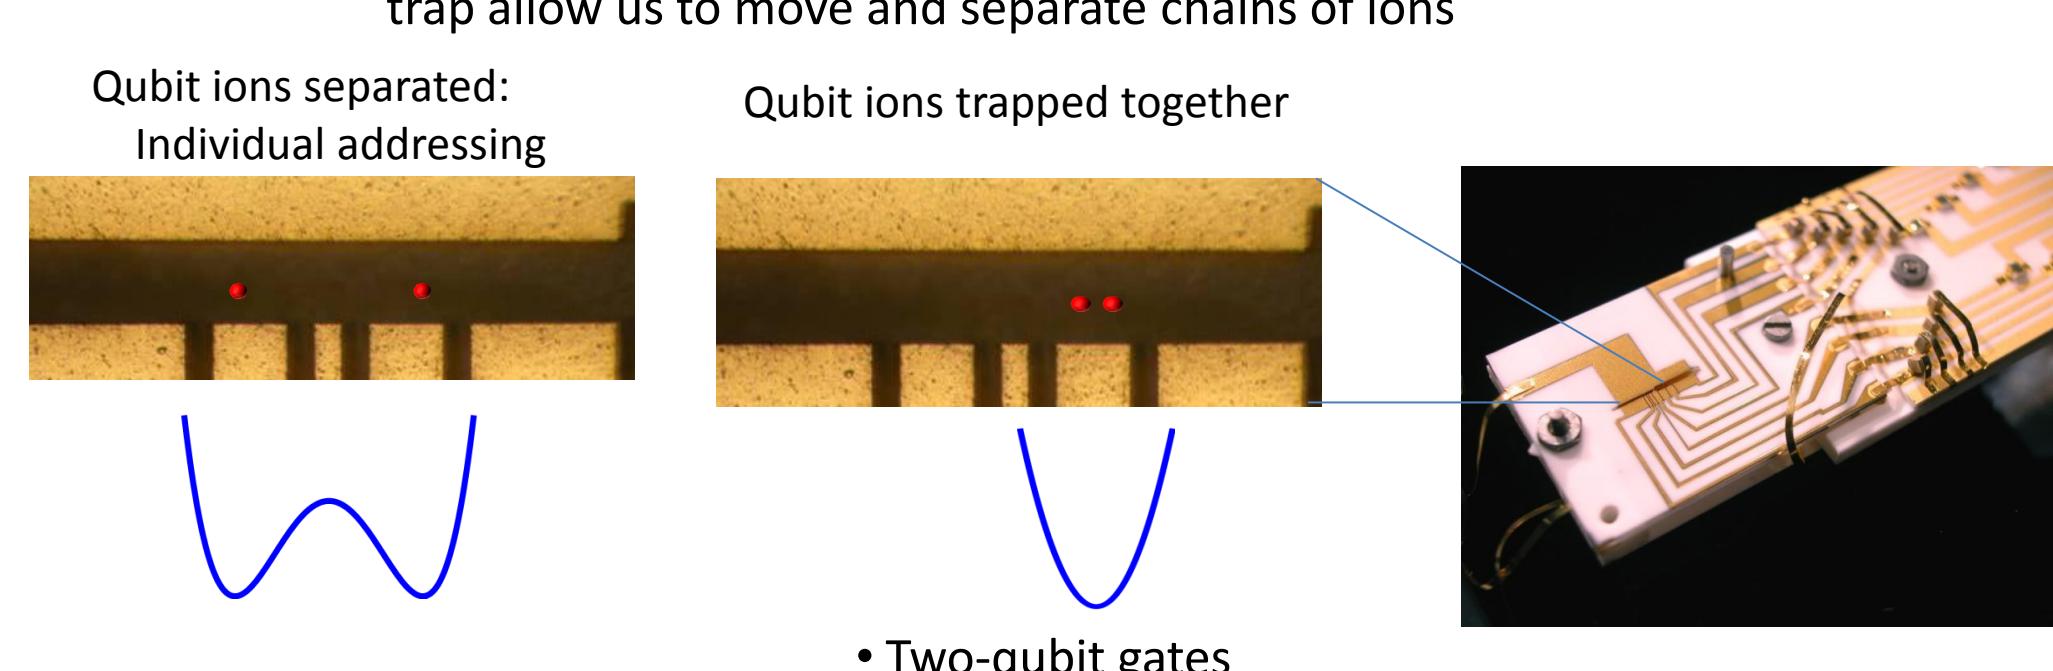

$$\hat{G} = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & i & 0 & 0 \\ 0 & 0 & i & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}$$

We demonstrate arbitrary control by choosing at random a unitary operator and one of 16 input states. We perform state-tomography on the output, and compare this to the ideal state

Multi-zone trap

Time varying voltages applied to electrodes of a segmented trap allow us to move and separate chains of ions

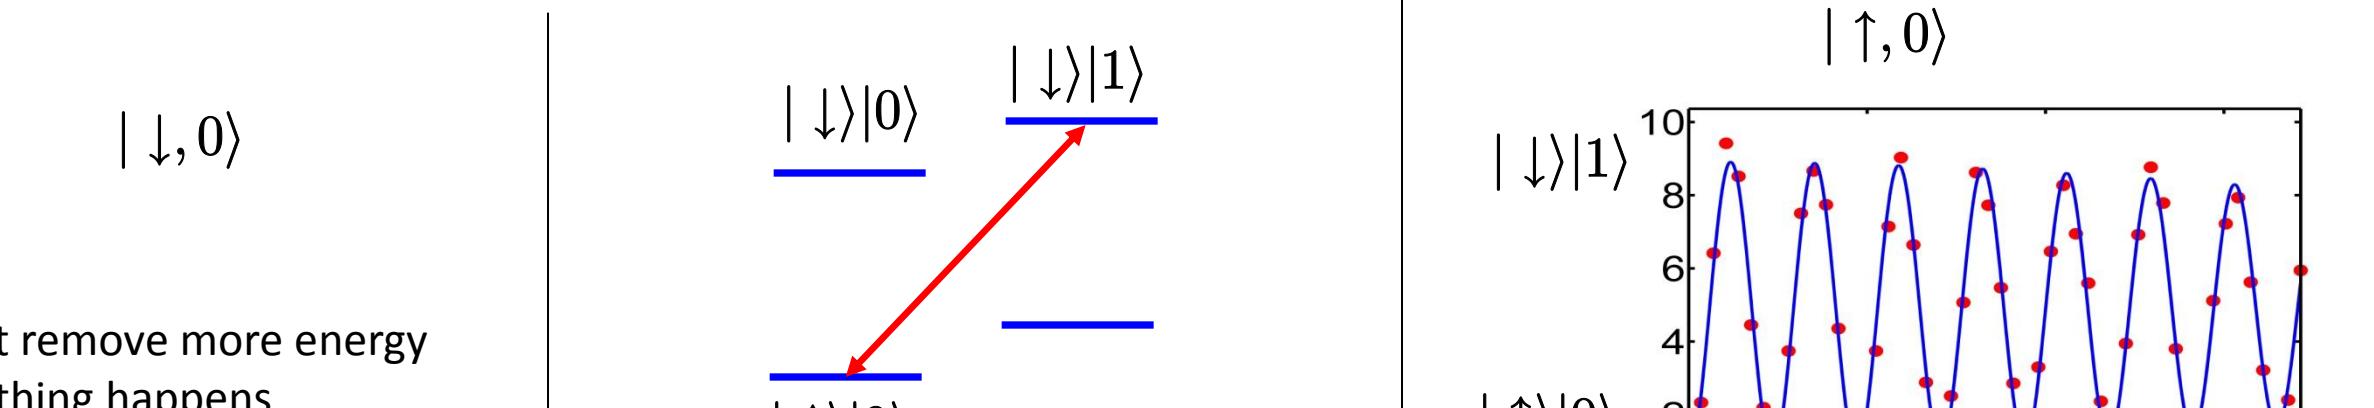

- Qubit readout
- Single-qubit gates

Entangled Mechanical Oscillators

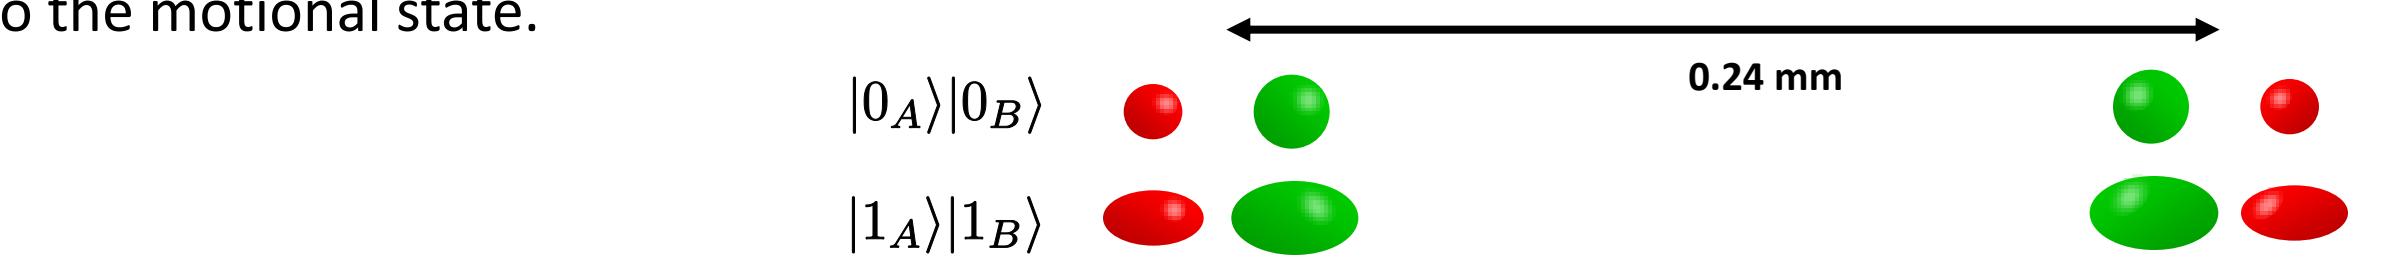

J.D.Jost et. al. *Nature* **459** 683-685 (2009)

- After entangling the internal states of two Beryllium ions, we can separate them, and use **sympathetic cooling** (see right) with Magnesium to initialise the ground state of motion in each trap

- We can then drive Rabi flopping on the motional sideband in each trap.

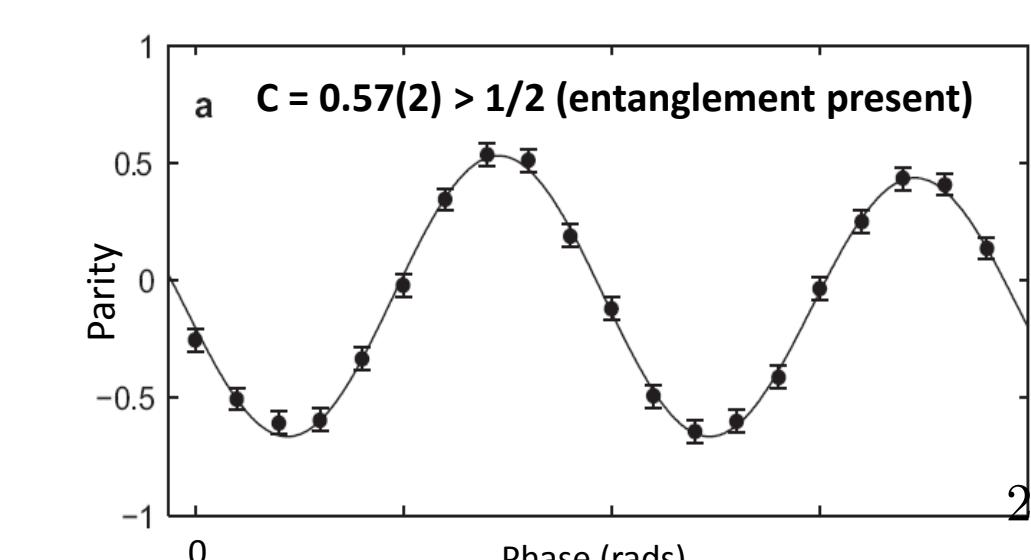

- By performing a "pi" pulse in each trap, we can map the internal state entanglement into the motional state.

$$\frac{1}{\sqrt{2}} [|0_A\rangle|0_B\rangle + |1_A\rangle|1_B\rangle]$$

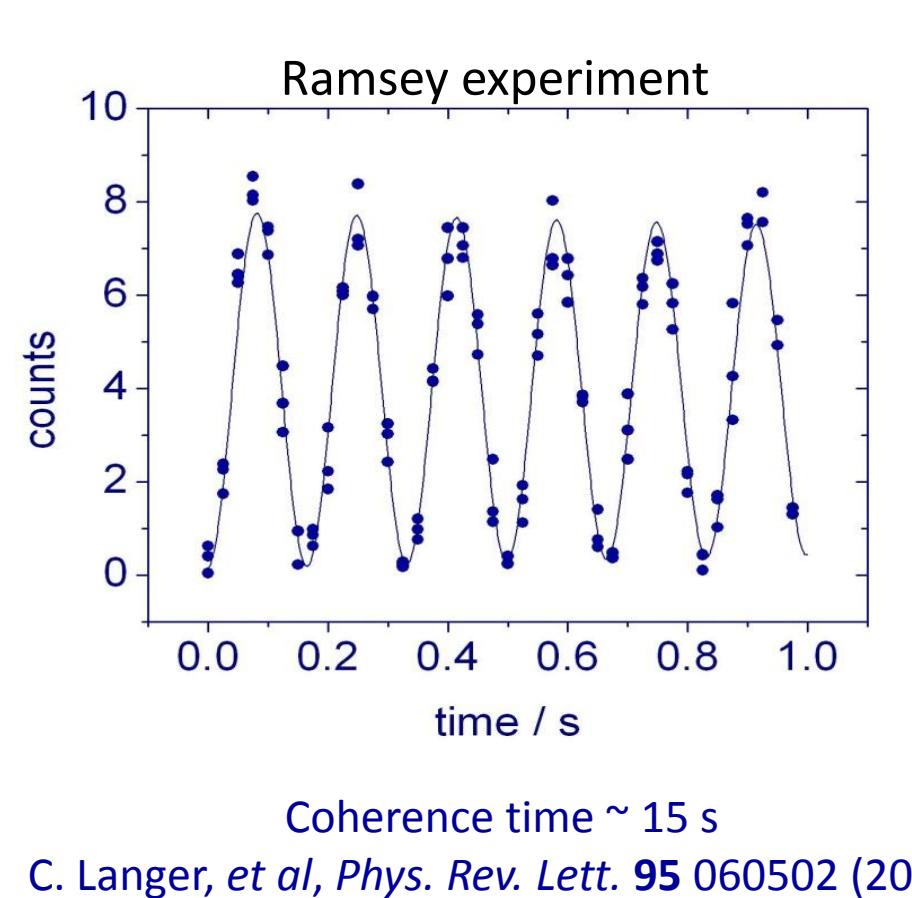

- We verify by reversing the mapping, and verifying the coherence element of the resulting spin density matrix.

Mapping in and out can be misleading – what if some population got left behind in the spin? We ensure that this doesn't contribute to C, by "shelving" this population in a state which doesn't interact with the phase-scanned analysis pulse

Scalable trapped ion quantum register

Long-lived qubits

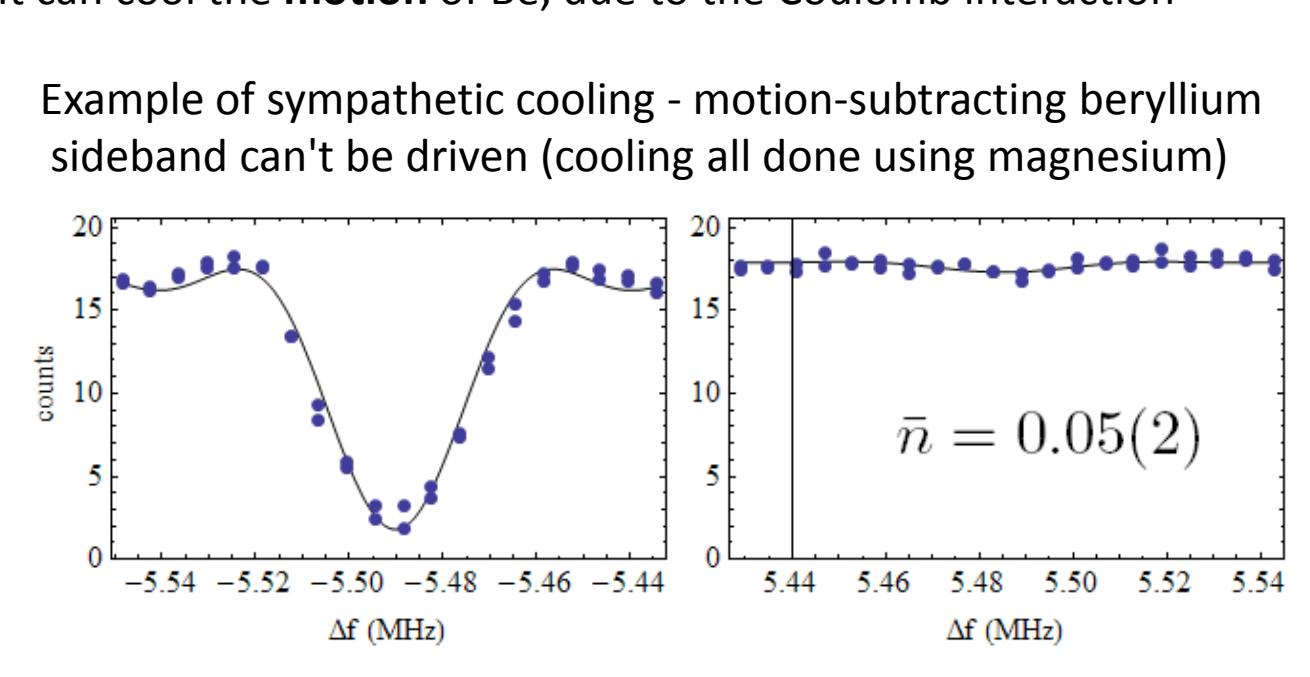

To control 2 qubits, we use a four ion crystal

Sympathetic cooling

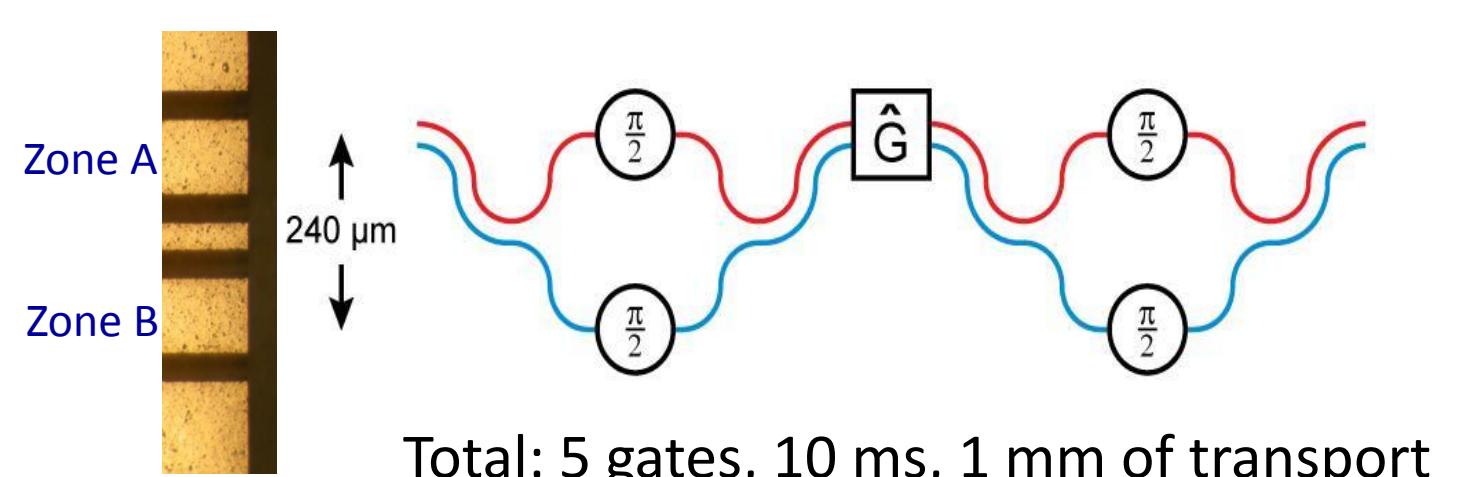

Cannot directly laser cool qubit ion - destroy qubit coherence
Instead – trap two species of ion

Mg light doesn't couple to internal Be (qubit) states
It can cool the **motion** of Be, due to the Coulomb interaction

Putting the pieces together

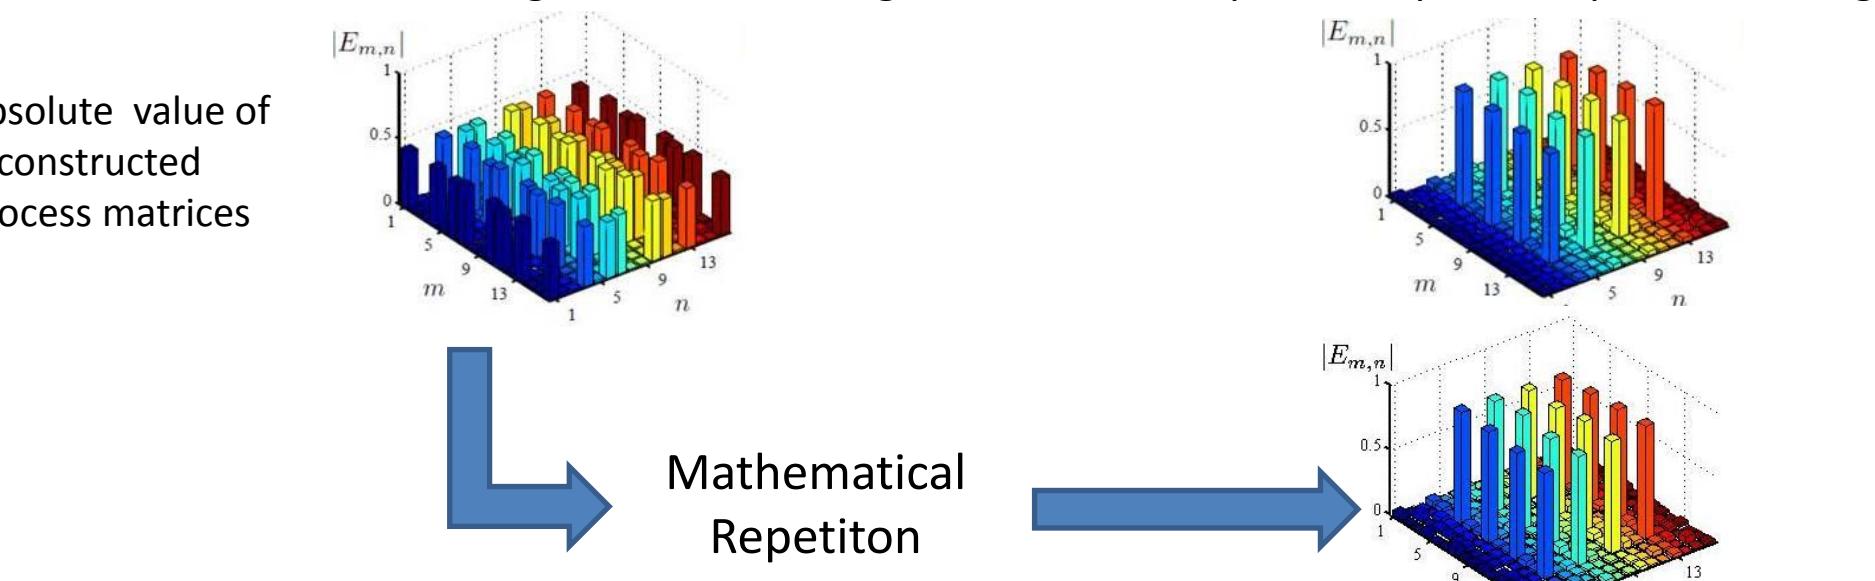

J. P. Home et al. *Science* **325**, 1227 (2009)

Characterization of repeatability of operation U, which involves a combination of tasks

$$\hat{U} \equiv \begin{array}{c} \text{R}(\theta, \phi) \quad \text{G} \quad \text{R}(\theta, \phi) \\ \text{R}(\theta, \phi) \quad \text{G} \quad \text{R}(\theta, \phi) \end{array}$$

Individual addressing for readout and gates allows us to perform quantum process tomography

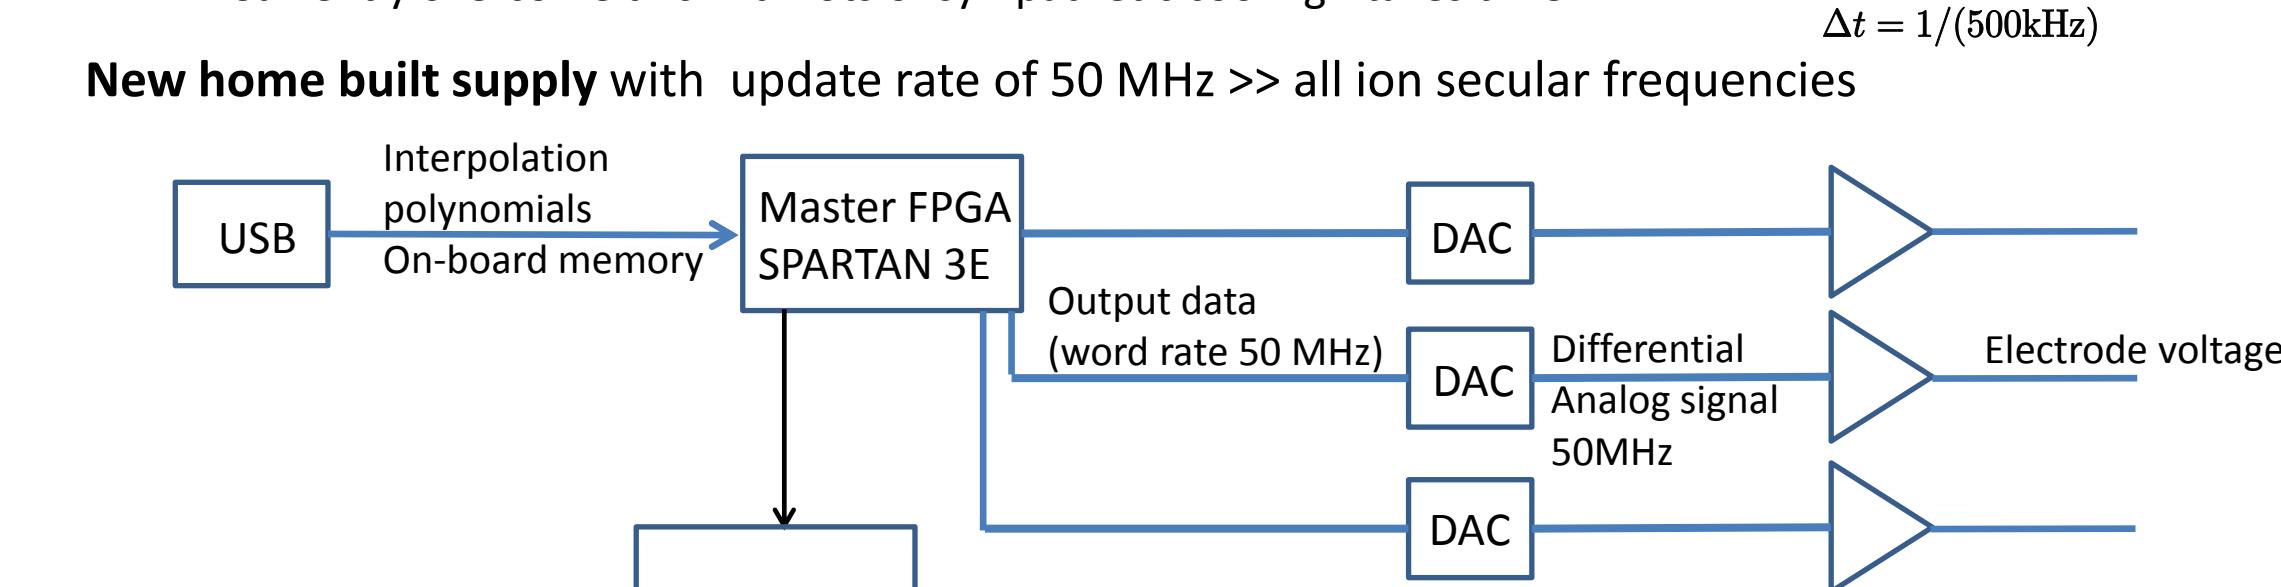

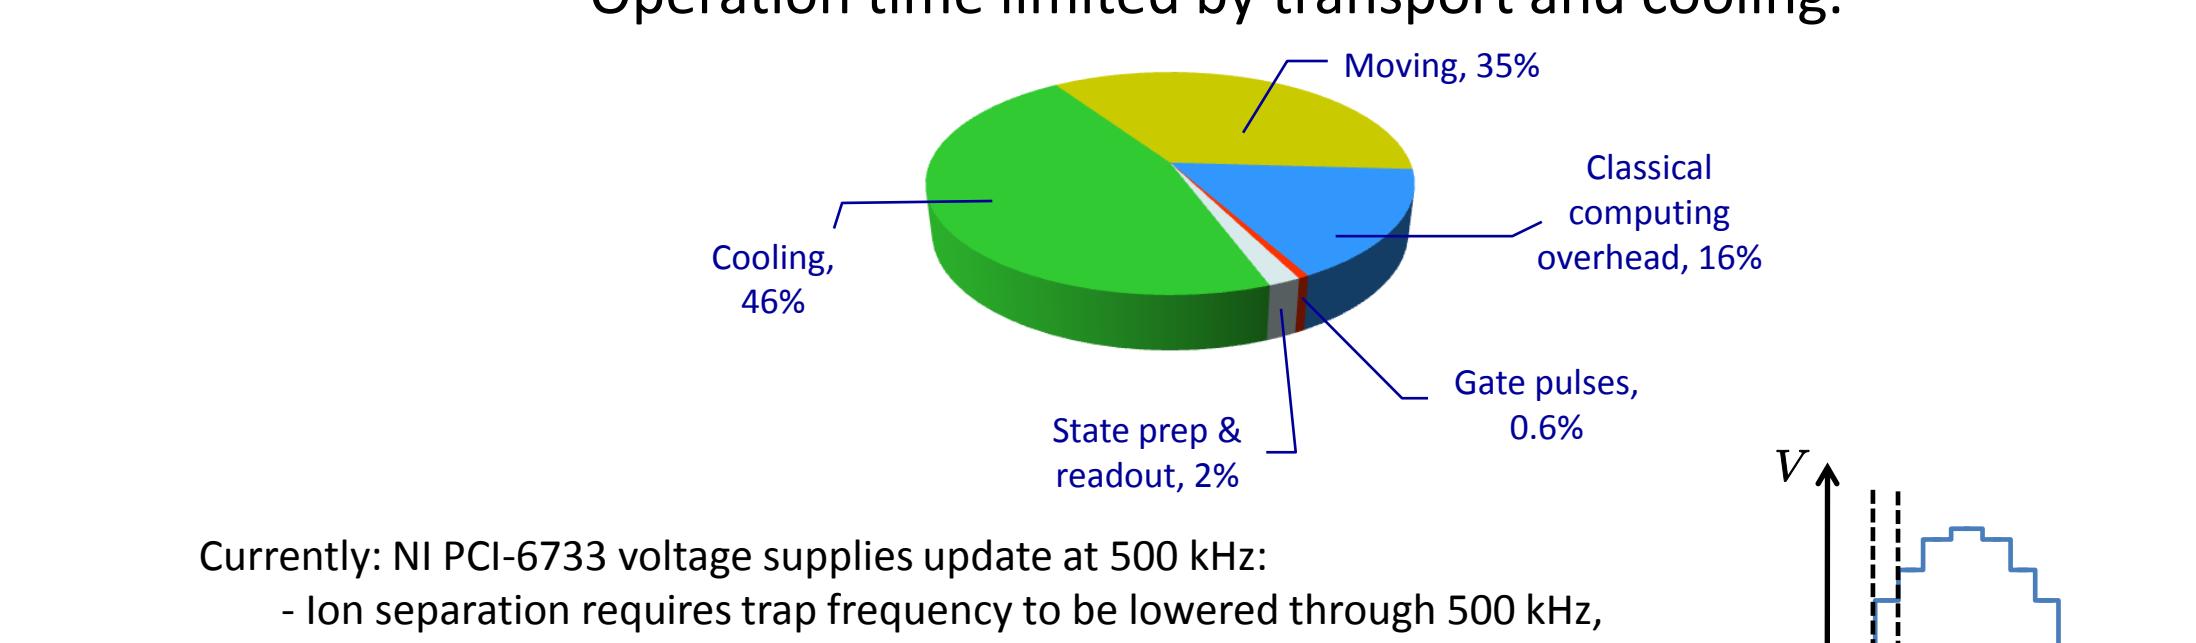

All operations are repeatable and can be interspersed

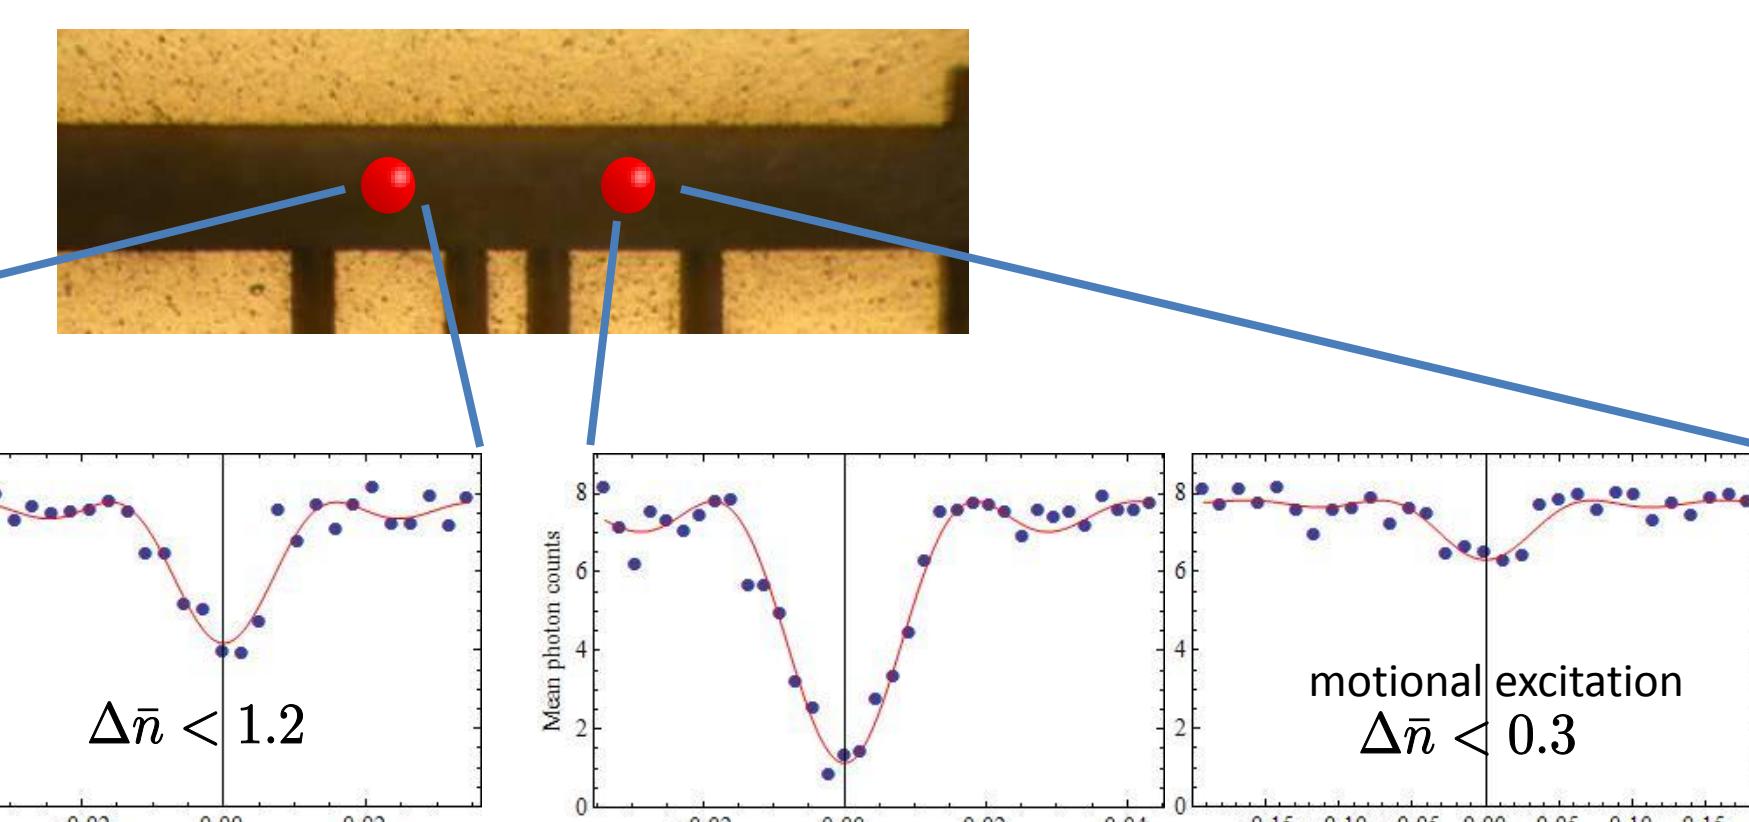

($f(\text{MaxLike})$ accounts for bias in Maximum Likelihood Estimation - problem for tomography methods)

Smooth voltage supplies for fast transport of ions

Operation time limited by transport and cooling.

Tested two channels by attaching to separation electrode only
- separation of two beryllium ions - record low amounts of heating!

Anharmonic trap potentials

Most work up until now assumes a harmonic potential well. This is generally a good approximation when the electrode size and ion-electrode distance p is large compared to the extent of the ion crystal. We observe effects on the motional modes due to higher order terms in the trapping potential, which will become more important with larger crystals and smaller traps.

$$V = \alpha_2 z^2 + \alpha_3 z^3 + \alpha_4 z^4$$

The curvature of the potential is now different at each ion

Odd-order anharmonicity - asymmetry results in different amplitudes for the beryllium ions for our four ion crystal

We observe beating when Rabi flopping on motional sidebands
